

Quantum Electrodynamics

QED

Particle Physics
Fabrice Couderc / Eli BenHaim

NPAC 2019

1. Introduction to quantum field theory (QFT)
 1. Introduction
 2. Scalar fields
 3. Dirac fields
 4. Electromagnetic field
2. Quantum electrodynamics (QED), an interacting field theory
 1. Interacting field theory
 2. Feynman diagrams
 3. ee to $mumu$ scattering
3. Renormalisation for experimentalists
 1. Preliminary
 2. Vertex correction
 3. Self-energy correction
 4. Vacuum polarisation
 5. First test of QED running coupling constant

- Quantum field theory (QFT) developed to solve
Special relativity + quantum mechanics
- Special relativity
 - ✓ $E = m c^2$
 - ✓ Can convert particle into energy and vice-versa
- Classical quantum mechanics
 - ✓ $\Psi(x)$ probability of finding a particle at point x
- QM+ SR
 - ✓ Probability for a single particle can not be conserved since the particle can disappear or appear...
 - ✓ Interpretation of $\Psi(x)$???
- QFT : interpret $\Psi(x)$ as an operator

- The interpretation of $\Psi(x)$ with the help of the classical quantum oscillator and the ladder operator
- For a real (*i.e.* neutral) scalar field

$$(\partial_\mu \partial^\mu - m^2)\phi(x) = (\square + m^2)\phi(x) = 0$$

$$\phi(x) = \int \frac{d^3 \vec{p}}{(2\pi)^3} \frac{1}{\sqrt{2 E_p}} (a_{\vec{p}} e^{-ip \cdot x} + a_{\vec{p}}^\dagger e^{+ip \cdot x})$$

$$p^0 = E_p = +\sqrt{m^2 + \vec{p}^2}$$

$$[a_{\vec{p}}, a_{\vec{k}}^\dagger] = (2\pi)^3 2 E_p \delta^{(3)}(\vec{p} - \vec{k})$$

For Lorentz invariance

- Charged scalar field (ϕ complex)
 - ✓ both ϕ and ϕ^* obey KG equation

$$\phi(x) = \int \frac{d^3 \vec{p}}{(2\pi)^3} \frac{1}{\sqrt{2 E_p}} (a_{\vec{p}} e^{-ip \cdot x} + b_{\vec{p}}^\dagger e^{+ip \cdot x})$$

$$\phi^\dagger(x) = \int \frac{d^3 \vec{p}}{(2\pi)^3} \frac{1}{\sqrt{2 E_p}} (b_{\vec{p}} e^{-ip \cdot x} + a_{\vec{p}}^\dagger e^{+ip \cdot x})$$

- a, b same commutation rules as for a real scalar field
 - ✓ a^\dagger (a) creates (destroys) a particle
 - ✓ b^\dagger (b) creates (annihilates) an anti-particle
- The electric charge is conserved (not the number of particles)

$$Q = \int \frac{d^3 p}{(2\pi)^3} \left(a_{\vec{p}}^\dagger a_{\vec{p}} - b_{\vec{p}}^\dagger b_{\vec{p}} \right)$$

N particles - M anti-particles = (N+M) q e

- Fermions field are bi-spinor and obey the Dirac equation

$$\psi(x) = \int \frac{d^3 \vec{p}}{(2\pi)^3} \frac{1}{\sqrt{2 E_{\vec{p}}}} \left(a_{\vec{p}}^s u^s(p) e^{-ip \cdot x} + b_{\vec{p}}^{s\dagger} v^s(p) e^{+ip \cdot x} \right)$$

$$\bar{\psi}(x) = \int \frac{d^3 \vec{p}}{(2\pi)^3} \frac{1}{\sqrt{2 E_{\vec{p}}}} \left(b_{\vec{p}}^s \bar{v}^s(p) e^{-ip \cdot x} + a_{\vec{p}}^{s\dagger} \bar{u}^s e^{+ip \cdot x} \right)$$

- u, v are the bi-spinor for fermions (anti-fermions)
 - ✓ note: s index corresponds to the spin (up or down)
- To respect causality; a, a⁺ and b, b⁺ must **anti-commute**

$$\{a_{\vec{p}}^s, a_{\vec{k}}^{r\dagger}\} = (2\pi)^3 2 E_p \delta^{(3)}(\vec{p} - \vec{k}) \delta_{rs}$$

- Show this implies: **(a⁺)² |0> = |0>**. Fermi statistics !

- Quantization done on the potential vector A^μ
- 4 scalar field obeying independently KG equations
- Quantization to be done respecting gauge invariance...
- A^μ a boson vector with spin 1
 - ✓ massless: only 2 state of helicity
- Euler Lagrange motion equation = Maxwell equations

$$A^\mu \equiv (V, \vec{A})$$

Show that

$$\partial_\mu F^{\mu\nu} = 0 \quad \text{With} \quad F_{\mu\nu} = \partial_\mu A_\nu - \partial_\nu A^\mu \equiv \begin{pmatrix} 0 & +E_x & +E_y & +E_z \\ -E_x & 0 & -B_z & +B_y \\ -E_y & +B_z & 0 & -B_x \\ -E_z & -B_y & +B_x & 0 \end{pmatrix}$$

And find back Maxwell equations for the interacting field

$$\partial_\mu F^{\mu\nu} = j^\nu \equiv (j^0 = \rho_q, \vec{j} = \vec{j}_q).$$

- Euler-Lagrange equations from the QED Lagrangian

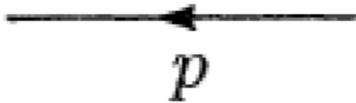

$$\begin{aligned}\mathcal{L}_{QED} &= \mathcal{L}_{Dirac} + \mathcal{L}_{Maxwell} + \mathcal{L}_{int} \\ &= \bar{\psi}(i\gamma^\mu\partial_\mu - m)\psi - \frac{1}{4}F_{\mu\nu}F^{\mu\nu} + Qe\bar{\psi}\gamma^\mu\psi A_\mu\end{aligned}$$

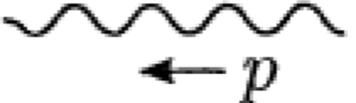

- The modified Euler-Lagrange equations when fields interact

$$\begin{aligned}(i\gamma^\mu\partial_\mu - m)\psi &= Qe A_\mu\gamma^\mu\psi \\ \partial_\mu F^{\mu\nu} &= Qe\bar{\psi}\gamma^\nu\psi\end{aligned}$$

QED Feynman rules (1) - propagator

- Propagator are actually « propagating » a particle from time-space point x to y
- Are derived from the free theory and used for internal lines in a diagram

Dirac propagator:  $= \frac{i(\not{p} + m)}{p^2 - m^2 + i\epsilon}$

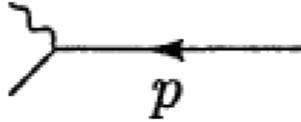

Photon propagator:  $= \frac{-ig_{\mu\nu}}{p^2 + i\epsilon}$

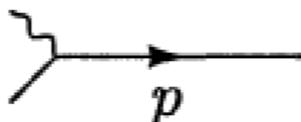

QED Feynman rules (2) - external lines

QED vertex:  $= iQe\gamma^\mu$

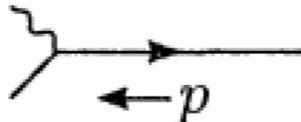

($Q = -1$ for an electron)

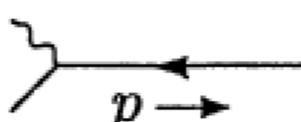

External fermions:

 $= u^s(p)$ (initial)

 $= \bar{u}^s(p)$ (final)

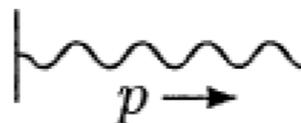

External antifermions:

 $= \bar{v}^s(p)$ (initial)

 $= v^s(p)$ (final)

External photons:

 $= \epsilon_\mu(p)$ (initial)

 $= \epsilon_\mu^*(p)$ (final)

A first example $e^+e^- \rightarrow \mu^+\mu^-$

$$\mathcal{M} = \bar{v}^{s'}(p') i Q e \gamma^\mu u^s(p) \frac{-i \eta_{\mu\nu}}{(p + p')^2} \bar{u}^r(k) i Q e \gamma^\nu v^{r'}(k') \propto Q^2 e^2$$

A first example $e^+e^- \rightarrow \mu^-\mu^+$

In the high energy limit, can easily demonstrate

$$\frac{d\sigma}{d\Omega} \propto \alpha^2 \left(1 + \cos^2 \theta \right)$$

Full computation gives (assuming $m_e = 0$). See the QFT course

$$\frac{d\sigma}{d\Omega} = \frac{\alpha^2}{4 s} \sqrt{1 - \frac{m_\mu^2}{E^2}} \left[\left(1 + \frac{m_\mu^2}{E^2} \right) + \left(1 + \frac{m_\mu^2}{E^2} \right) \cos^2 \theta \right]$$

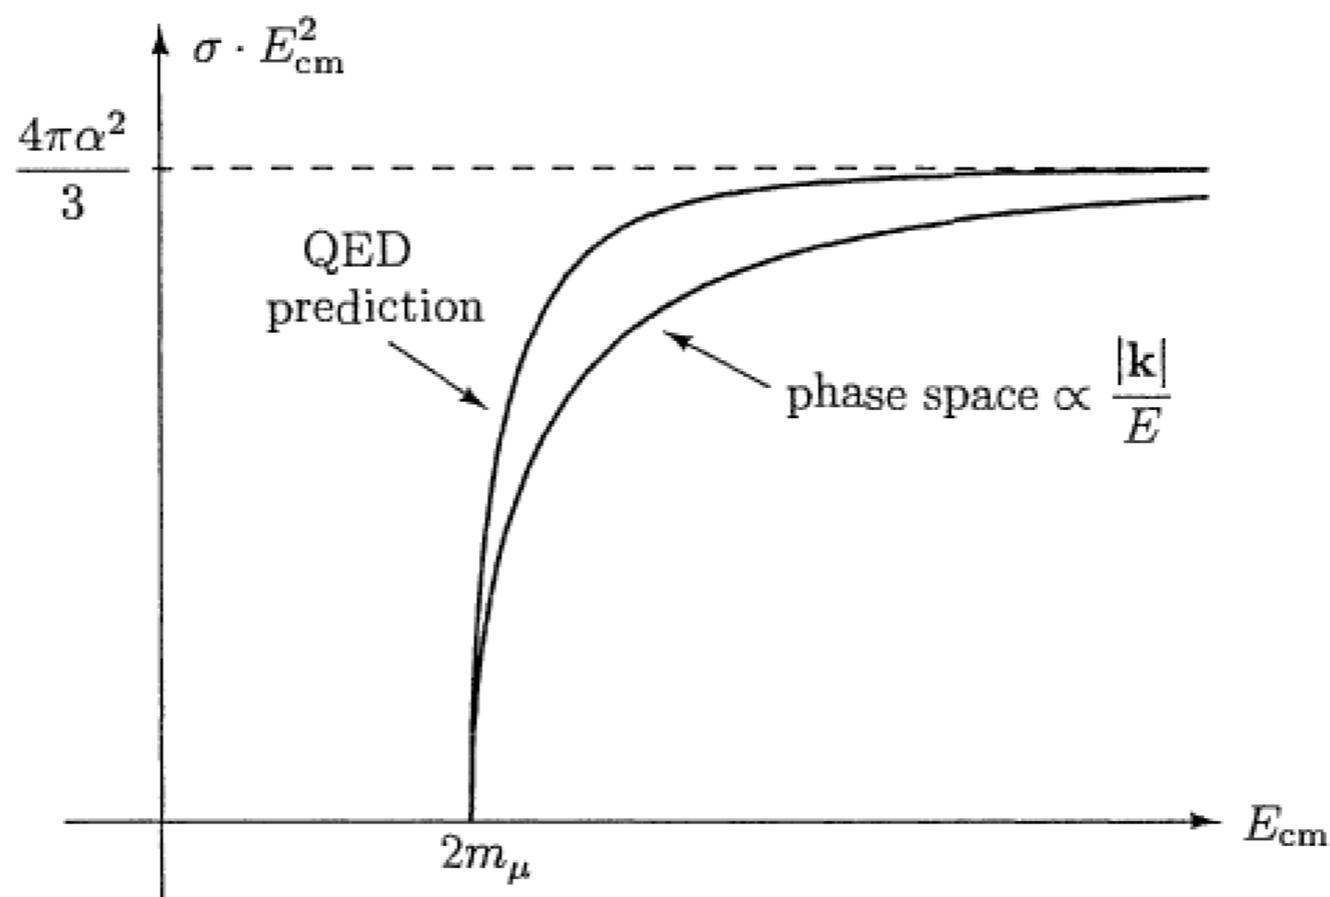

$$\sigma_{tot} = \frac{4\pi \alpha^2}{3 s} \sqrt{1 - \frac{m_\mu^2}{E^2}} \left(1 + \frac{m_\mu^2}{E^2} \right)$$

With $2E = \sqrt{s}$

Phase space

Matrix element

A first example $e^+e^- \rightarrow \mu^-\mu^+$

R ratio in e^+e^- collisions

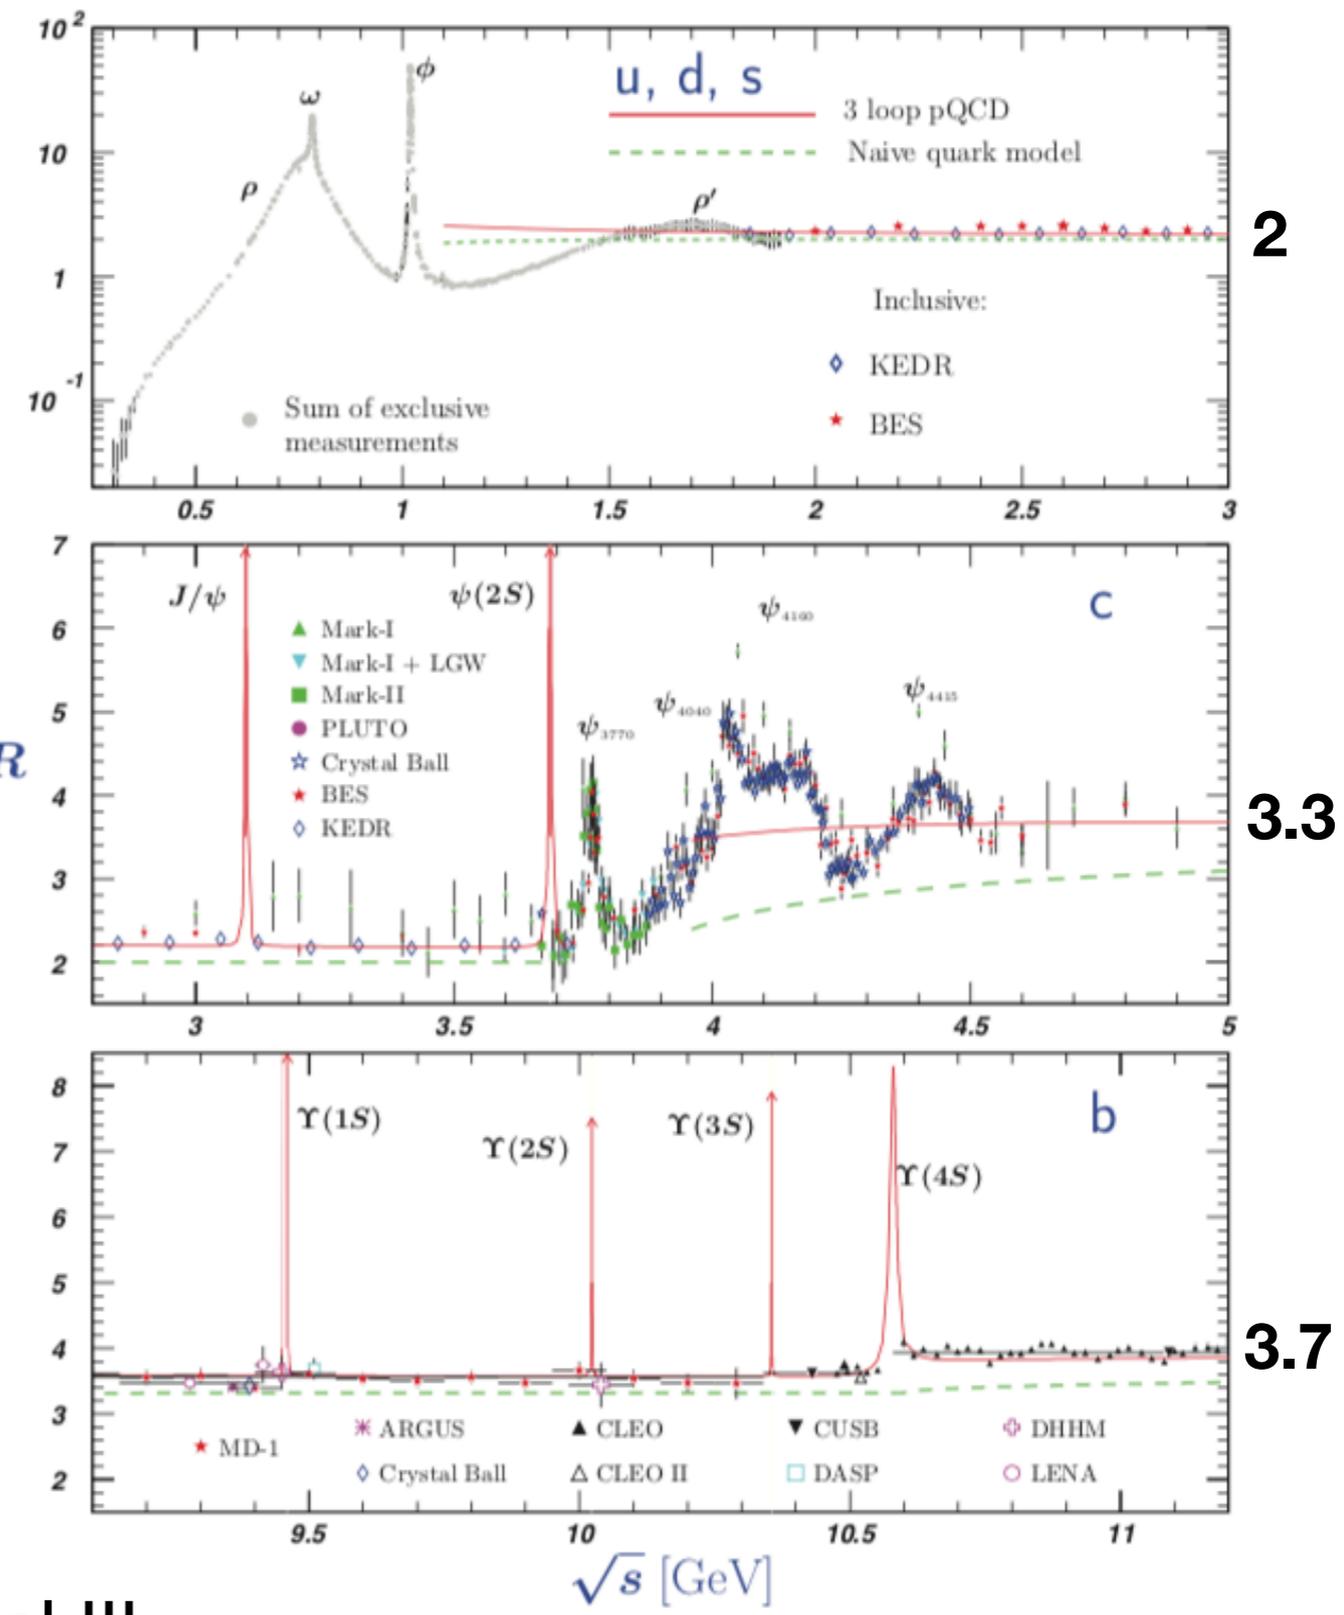

$$R_{had} = \frac{\sigma(e^+e^- \rightarrow hadrons)}{\sigma(e^+e^- \rightarrow \mu^+\mu^-)}$$

Show that in the quark model

$$\sqrt{s} < 2m_c \Rightarrow R_{had} = 2$$

$$\sqrt{s} < 2m_b \Rightarrow R_{had} = 3.3$$

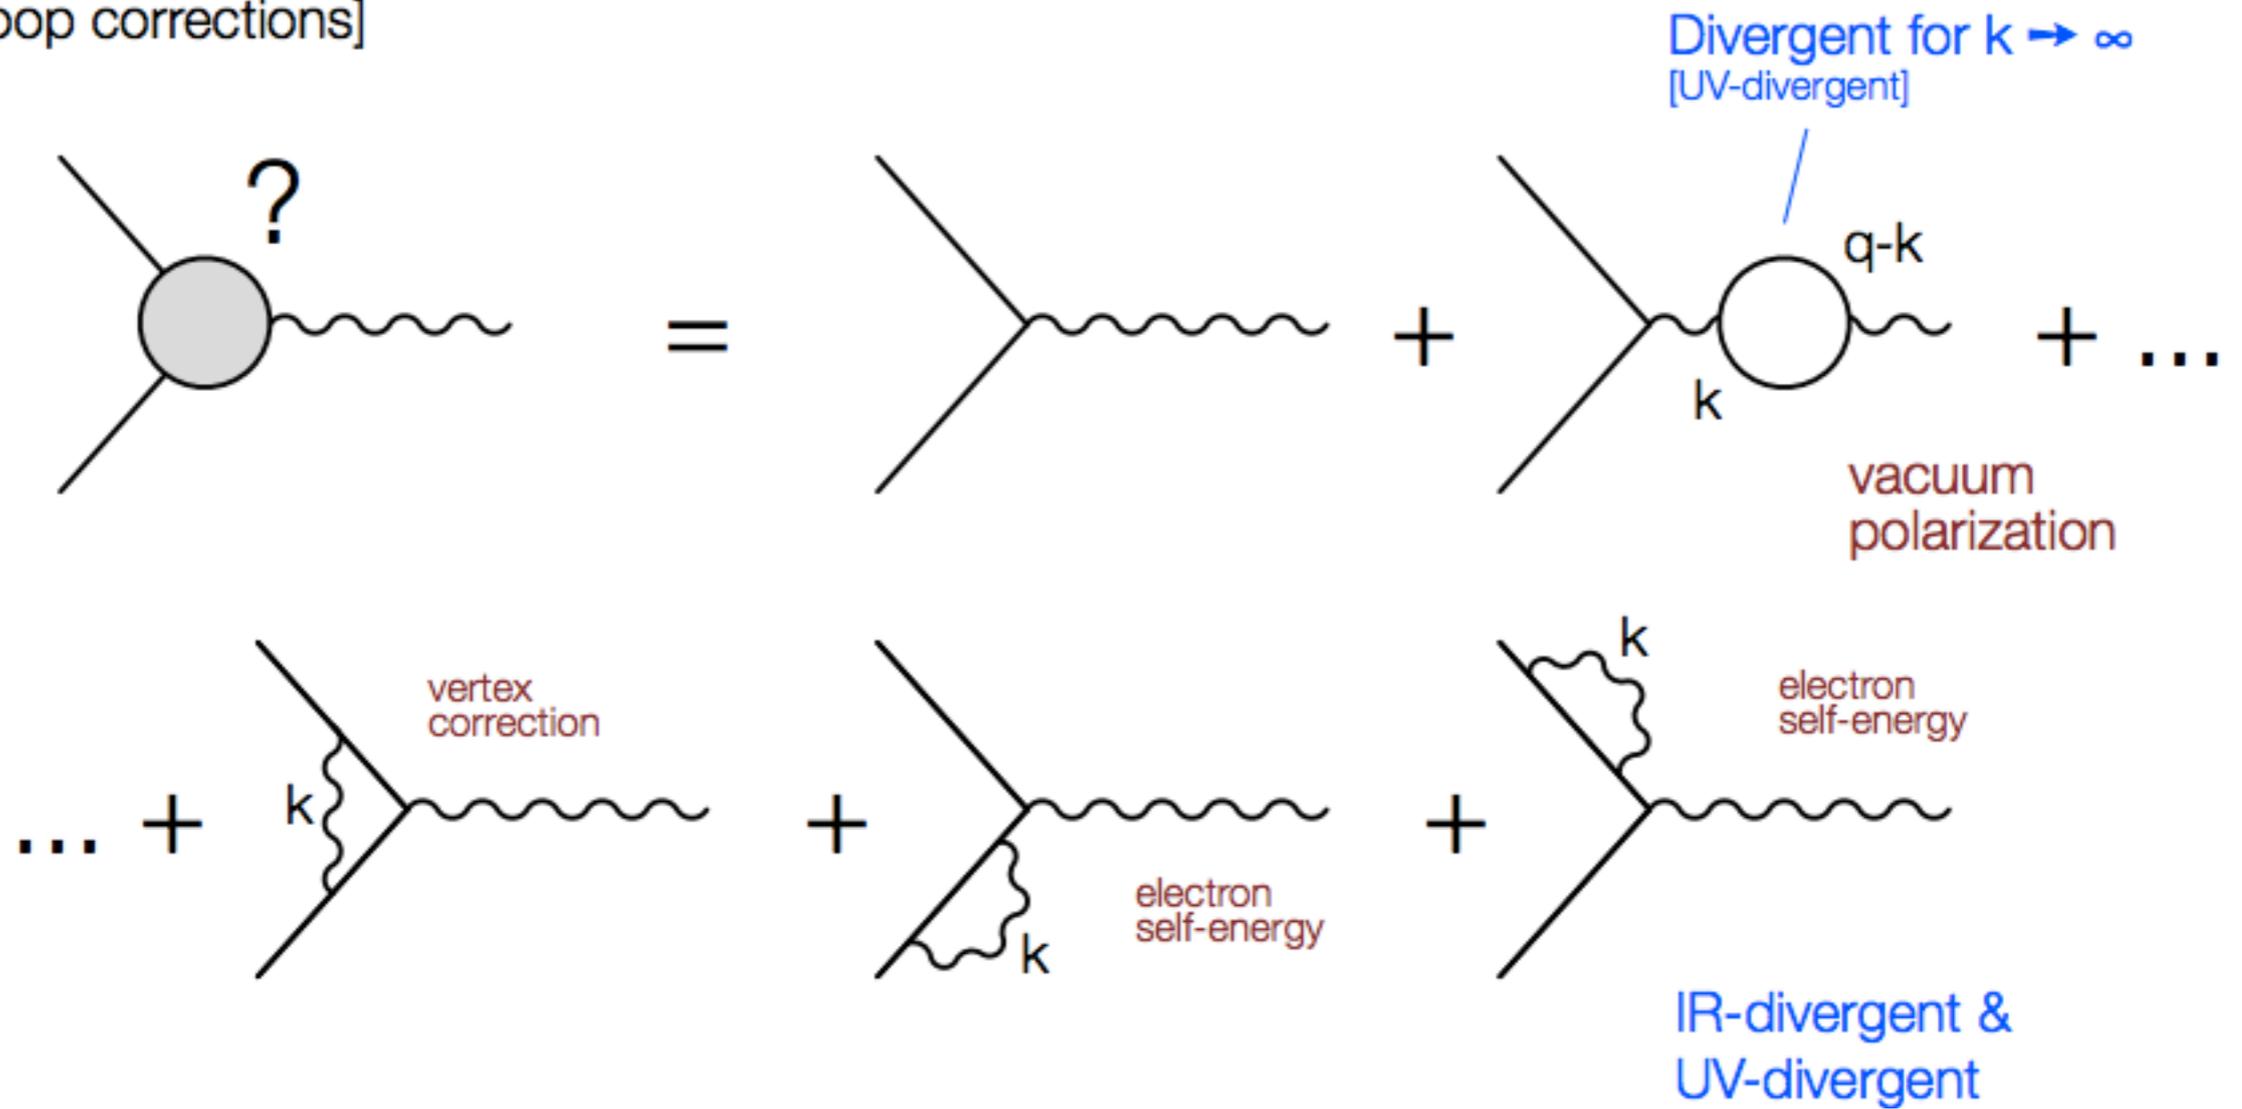

$$\sqrt{s} < 2m_t \Rightarrow R_{had} = 3.7$$

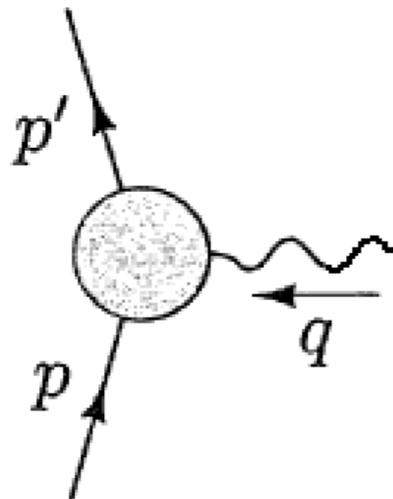

Very big success of the quark model !!!

Corrections to the QED vertex

Renormalization in QED:
 [1-loop corrections]

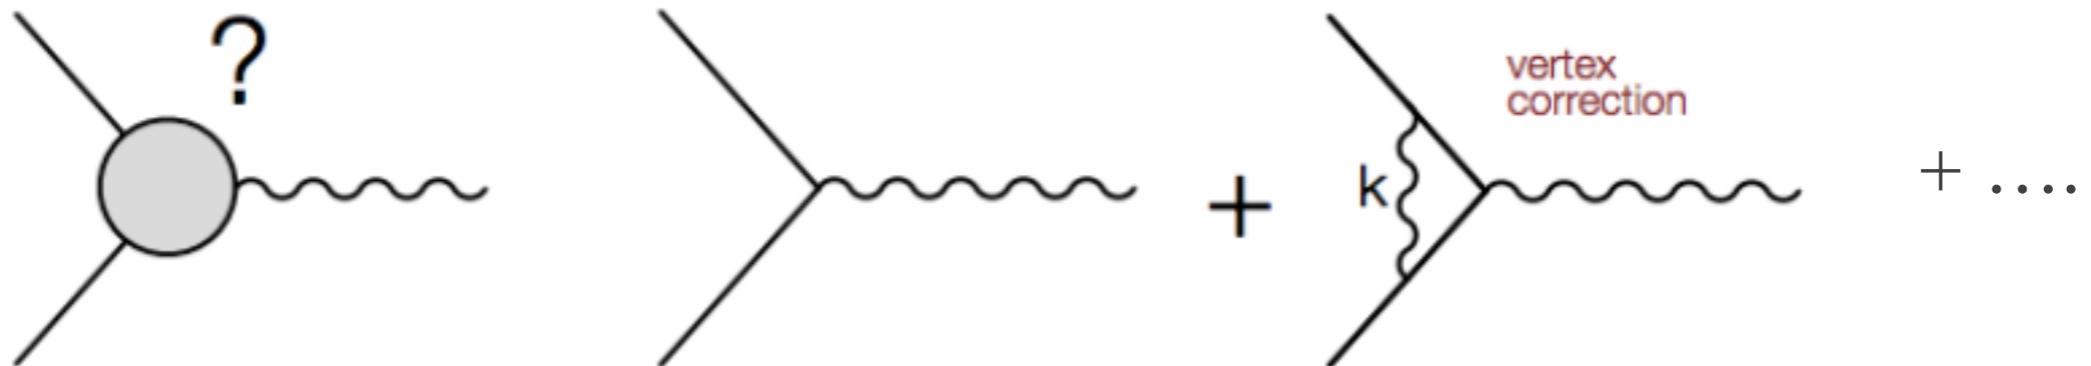

General form for vertex

$$-ie\gamma^\mu \rightarrow -ie\Gamma^\mu$$

$$\Gamma^\mu(q = p' - p) = \gamma^\mu F_1(q^2) + \frac{i \sigma^{\mu\nu} q_\nu}{2m} F_2(q^2)$$

Tree level: $F_1(q^2) = 1$; $F_2(q^2) = 0$

The second term modifies the electron coupling to a classical B field.

At NLO, vertex correction

$$F_1(q^2) = 1 - \delta F_1(q^2=0) + \delta F_1^{\text{IR}}(q^2)$$

$$F_2(q^2) = 0 + \alpha/2\pi \times [1(q^2 \rightarrow 0)]$$

F_1 diverges at low (IR) and high (UV) q^2

F_2 does not diverge!

$$a_e = (g-2)/2 = F_2(0) = \alpha/(2\pi) = 0.001161$$

$$a_e^{QED} = C_1 \left(\frac{\alpha}{\pi}\right) + C_2 \left(\frac{\alpha}{\pi}\right)^2 + C_3 \left(\frac{\alpha}{\pi}\right)^3 + C_4 \left(\frac{\alpha}{\pi}\right)^4 + C_5 \left(\frac{\alpha}{\pi}\right)^5 + \dots$$

C_4 891 diagrams, C_5 12672 diagrams (precision 3%) !!!

dominant

small terms (i.e. $\leq 3 \times 10^{-12}$)

$$a_e^{SM} = a_e^{QED} \overbrace{+ a_e^{QED}(\mu) + a_e^{QED}(\tau) + a_e^{QED}(\mu, \tau) + a_e(\text{hadr}) + a_e(\text{weak})}$$

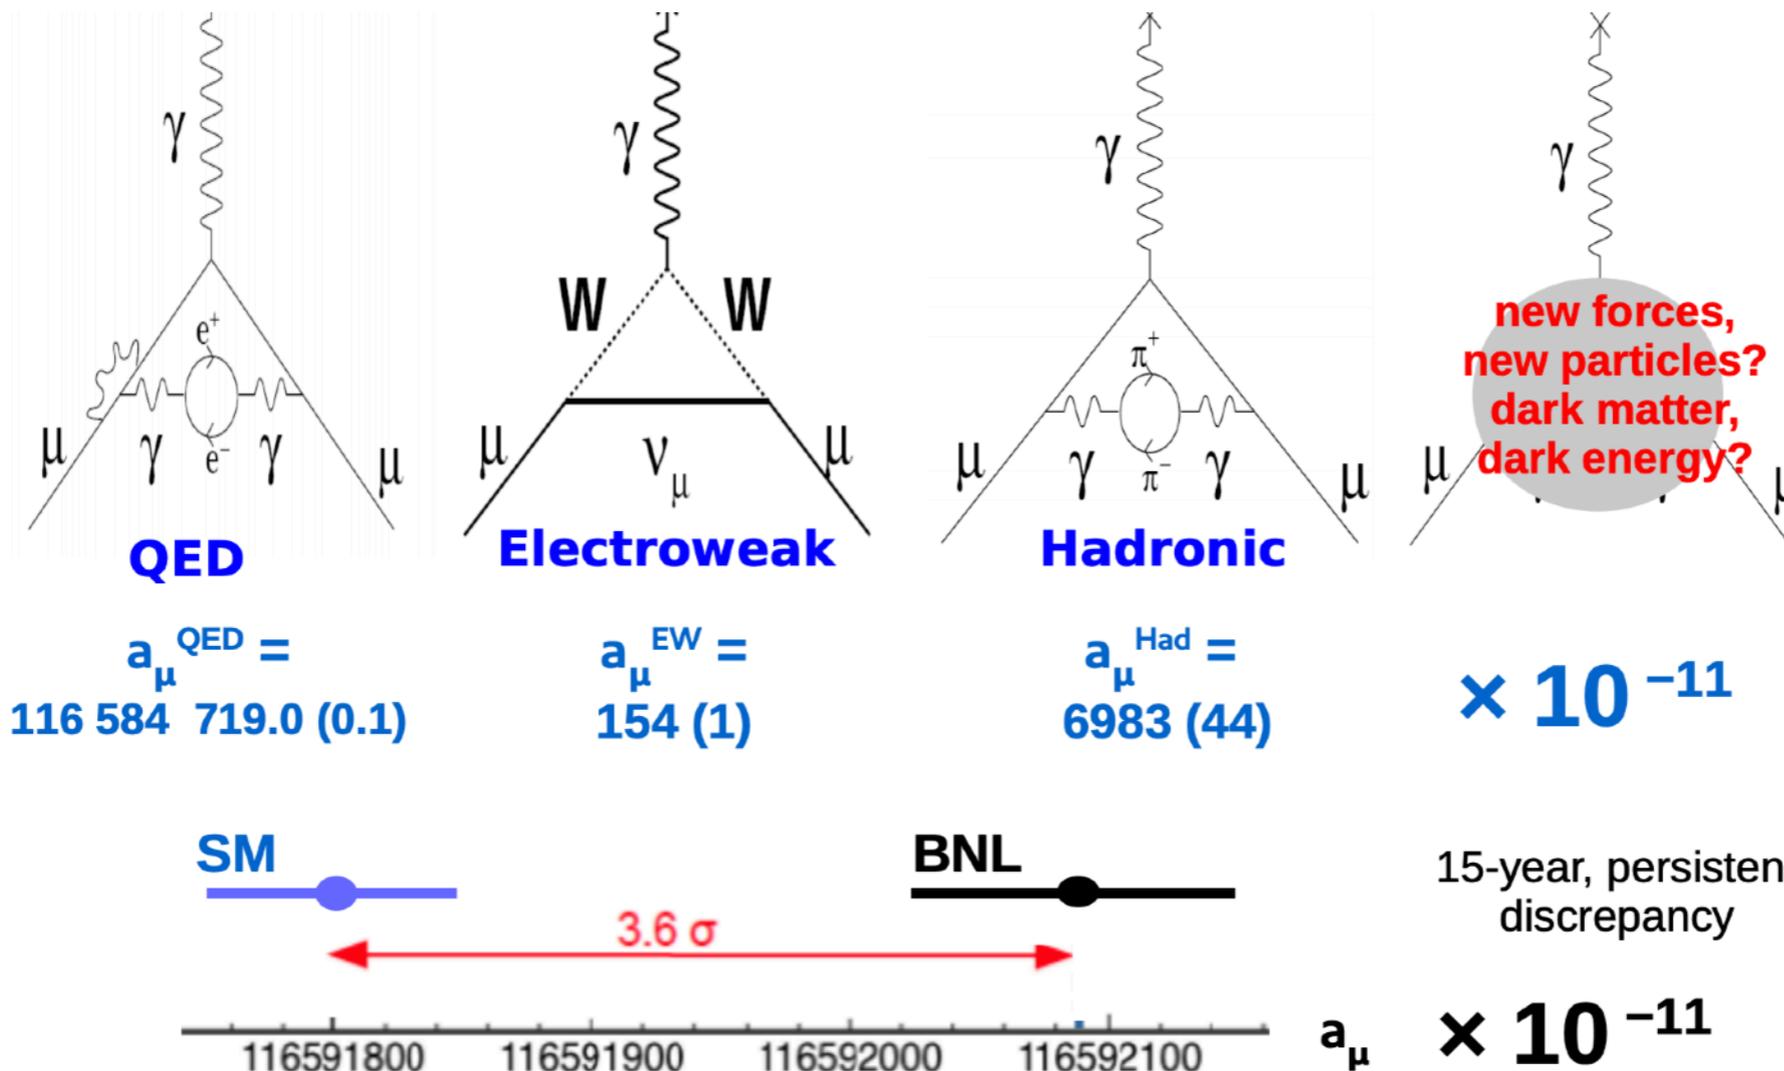

$$a_e^{SM}(\alpha) = 1\,159\,652\,182.031(15)(15)(720) \times 10^{-12}$$

$$a_e^{exp} = 1\,159\,652\,180.730(280) \times 10^{-12} \quad 0.25 \text{ ppb}$$

$$a_e^{SM}(\alpha) - a_e^{exp} = 1.30(77) \times 10^{-12} \quad 1.6 \sigma \text{ agreement}$$

Best measurement: D. Hanneke et al, Phys. Rev. Lett. 100, 120801 (2008)

Muon anomalous g-2

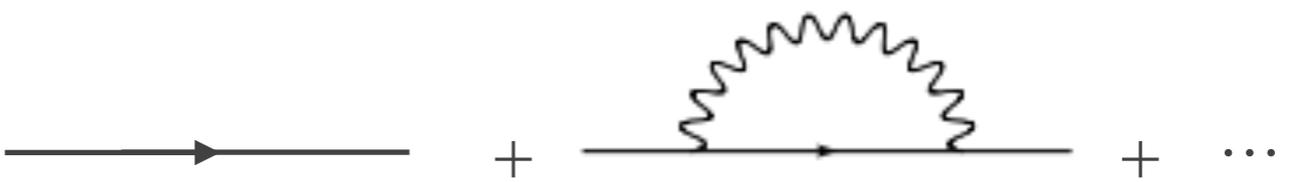

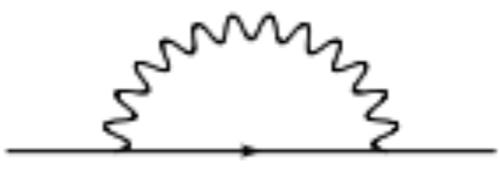

BNL: G. W. Bennett et al, Phys Rev D 73, 072003 (2006)

For muon the EW and hadronic contribution are not negligible.

Long standing oscillating discrepancy between 2 and 3 σ .

Lively field both on theory side (hadron contribution, LxL diagrams) and experimental side (Fermilab starting to take data, J-PARC approved)

Electron self energy $S_F(p) =$  $+$  $+$ \dots

Loop corrections have 2 effects

1. shift the pole in the propagator, *i.e.* change the electron mass
2. change the electron field strength by a factor $\sqrt{Z_2}$

Find the divergence of the loop diagram by dimensional arguments.

In fact **pole mass only shifted by $+\log(\infty)$** (bare mass is infinite),

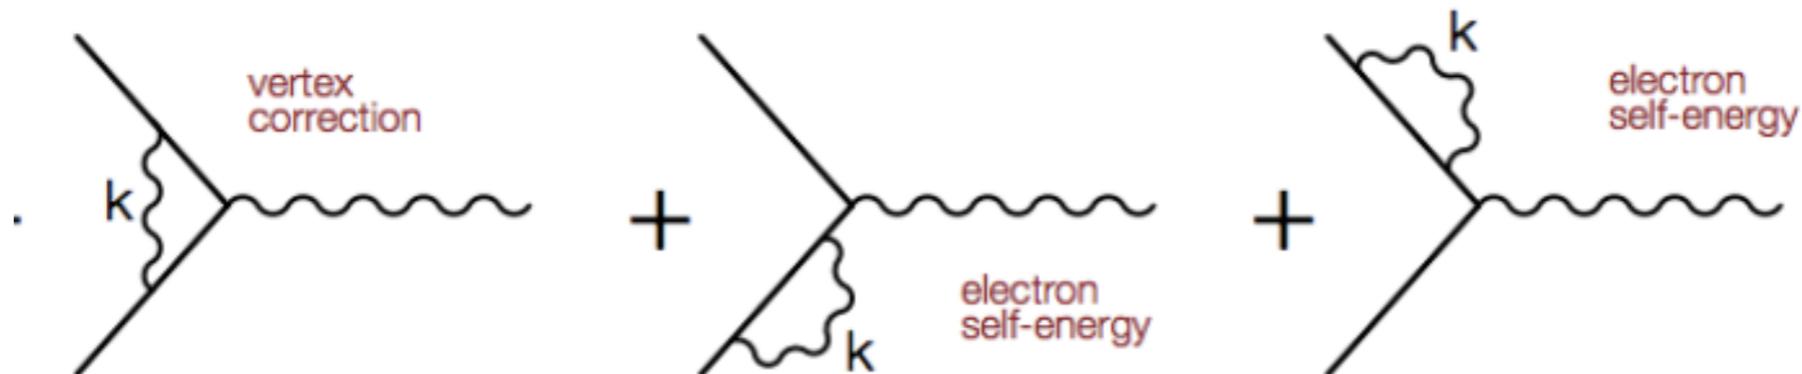

$$Z_2 = 1 + \delta Z_2(q^2=0) + \delta Z_2(q^2)$$

Z_2 also UV divergent, but
 $\delta Z_2(q^2)$ is not diverging

$\delta Z_2(q^2=0)$ diverges but fortunately

$$\delta Z_2(q^2=0) = \delta F_1(q^2=0)$$

$$\bar{u}(p') \Gamma^\mu(q) u(p) \rightarrow \left(\sqrt{Z_2} \bar{u}(p') \right) \Gamma^\mu(q) \left(\sqrt{Z_2} u(p) \right)$$

UV divergences cancels out!

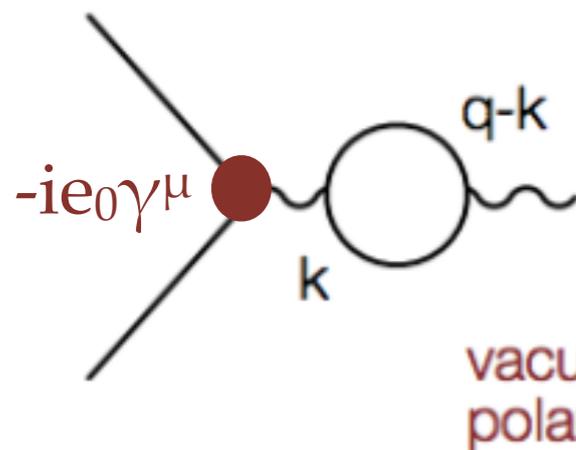

In fact : true to all orders thanks to gauge properties

$$Z_2 = 1 + \delta Z_2(q^2=0) + \delta Z_2(q^2)$$

$$F_1(q^2) = 1 - \delta F_1(q^2=0) + \delta F_1^{\text{IR}}(q^2)$$

$$\delta Z_2(q^2=0) = \delta F_1(q^2=0)$$

$$\bar{u}(p') \Gamma^\mu(q) u(p) \rightarrow \left(\sqrt{Z_2} \bar{u}(p') \right) \Gamma^\mu(q) \left(\sqrt{Z_2} u(p) \right)$$

$$\frac{-i\eta^{\mu\nu}}{q^2 + i\epsilon} \rightarrow \frac{-i\eta^{\mu\nu}}{q^2 + i\epsilon} \frac{1}{1 - \Pi(q^2)}$$

Dimension regularization
 $\Pi(q^2=0) = -2\alpha/(3\pi\epsilon)$
 UV divergence!

Do not change the propagator, but absorb $(1-\Pi)$ in the electron charge definition

$$\alpha(q^2) = \frac{e_0^2}{4\pi} \frac{1}{1 - \Pi(q^2)}$$

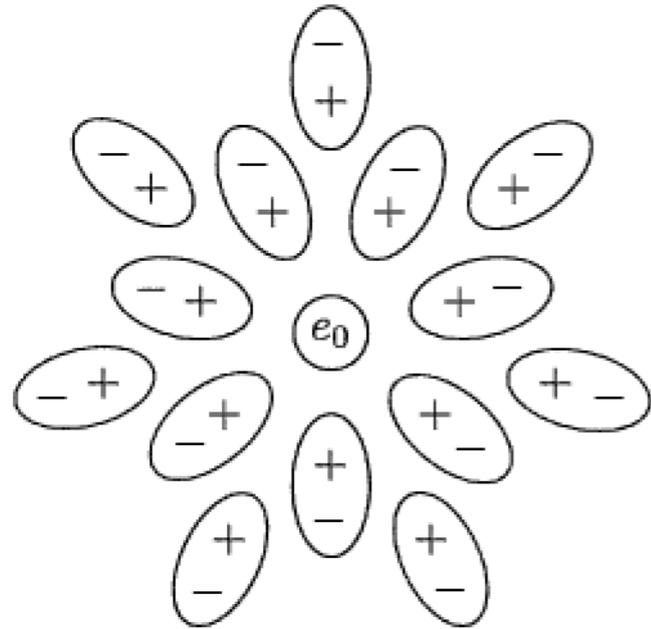

$$\alpha_{\text{eff}}(q^2) = \alpha(q^2 = 0) \frac{1}{1 - \Pi(q^2) - \Pi(0)}$$

Bare electron charge is infinite but it's absorbed in $\alpha(q^2 = 0)$

Electron charge depends on q^2 of the photon probe!

\Rightarrow coupling constants are running in QFT!

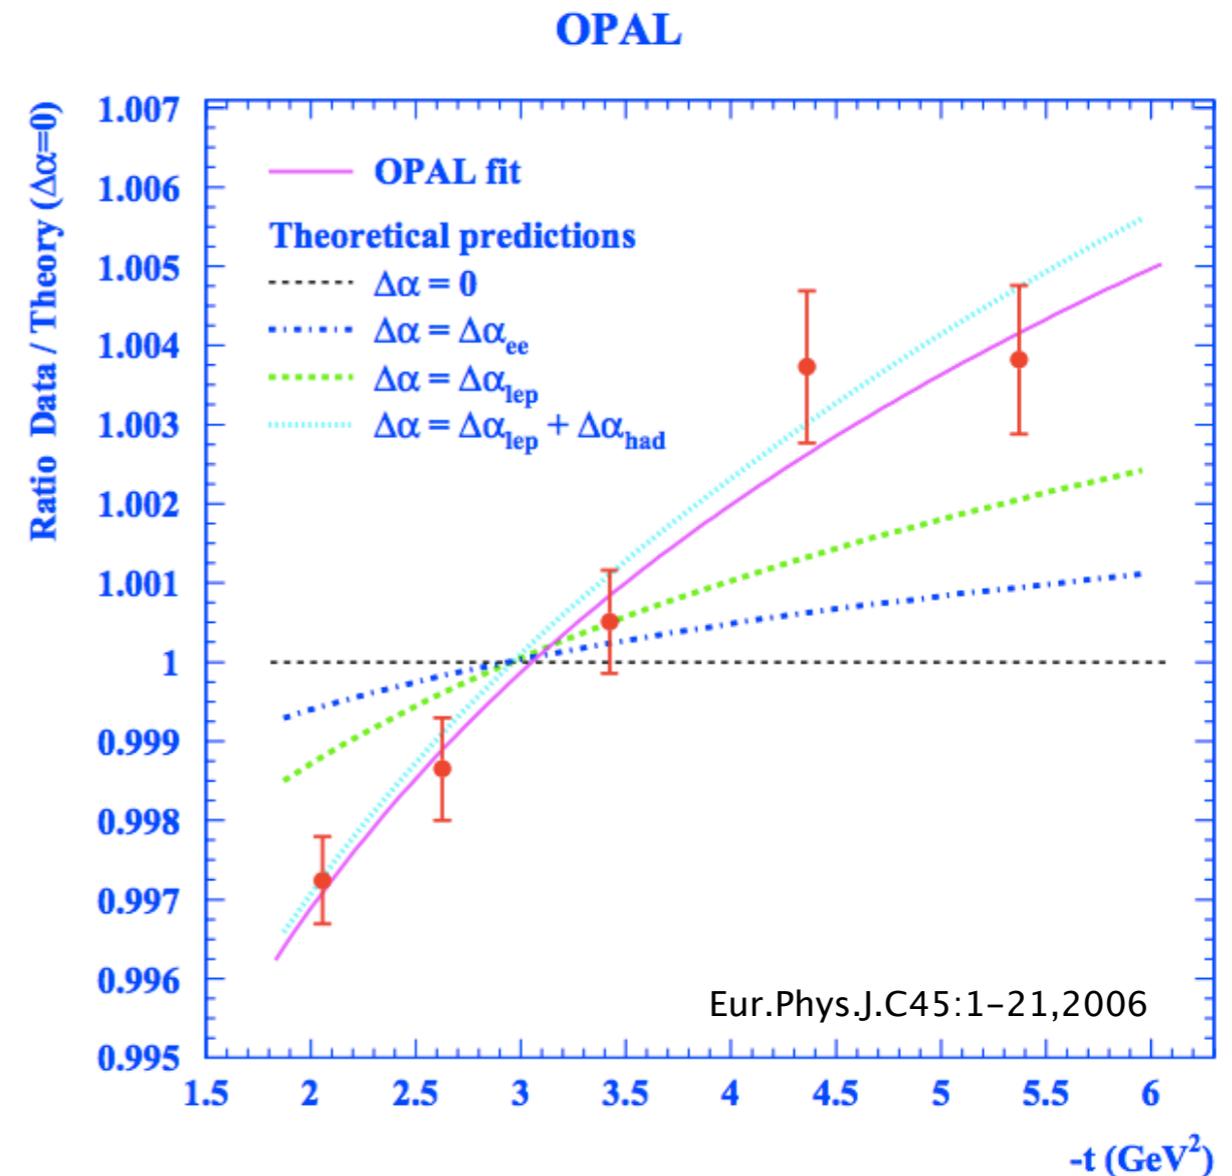

Screening effect

$$\alpha_{eff}(q^2) = \frac{\alpha}{1 - \frac{\alpha}{3\pi} \sum_f Q_f^2 \log\left(\frac{-q^2}{m_f^2}\right)}$$

$$\alpha(q^2 = 0) = 1/137$$

$$\alpha(q^2 = M_Z^2) = 1/128$$

Obtained from Bhabha scattering

Measurement of the Electromagnetic Coupling at Large Momentum Transfer

PRL78, 424 (1997)

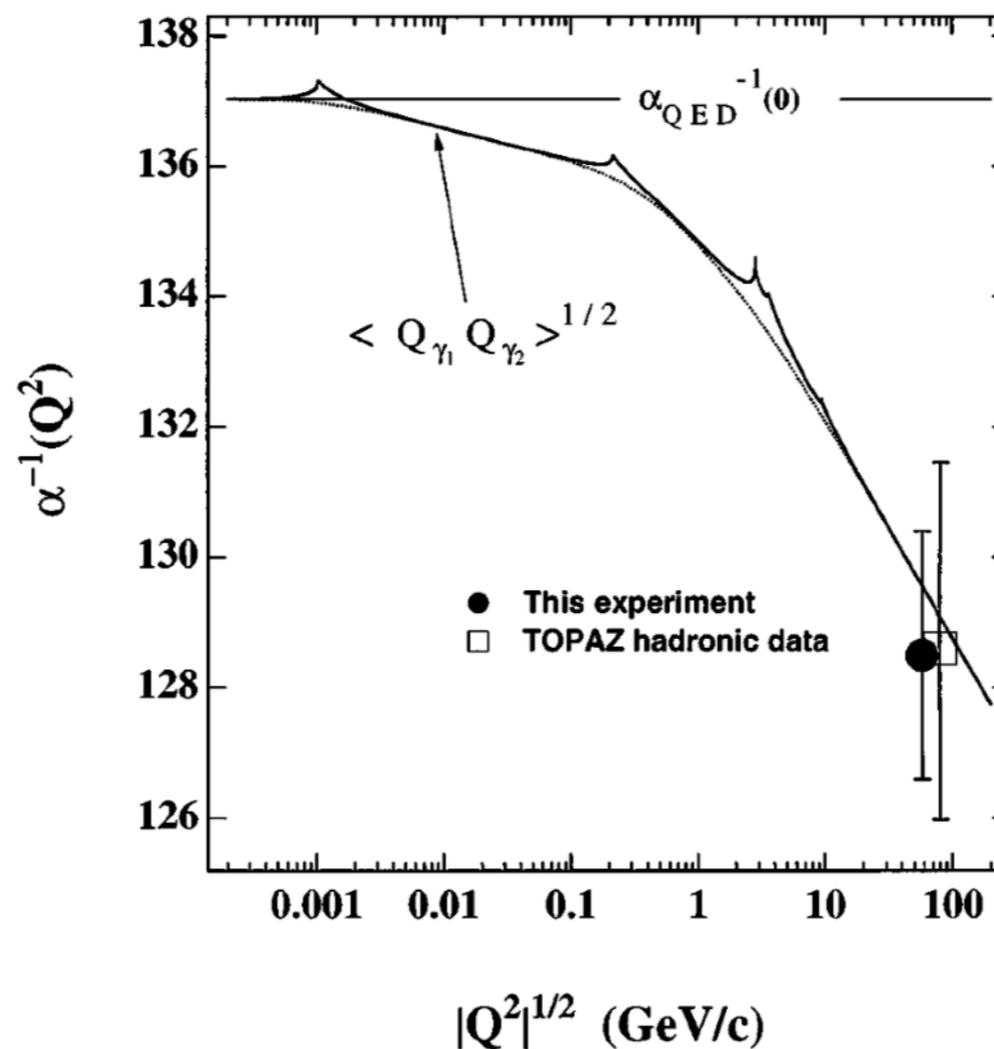

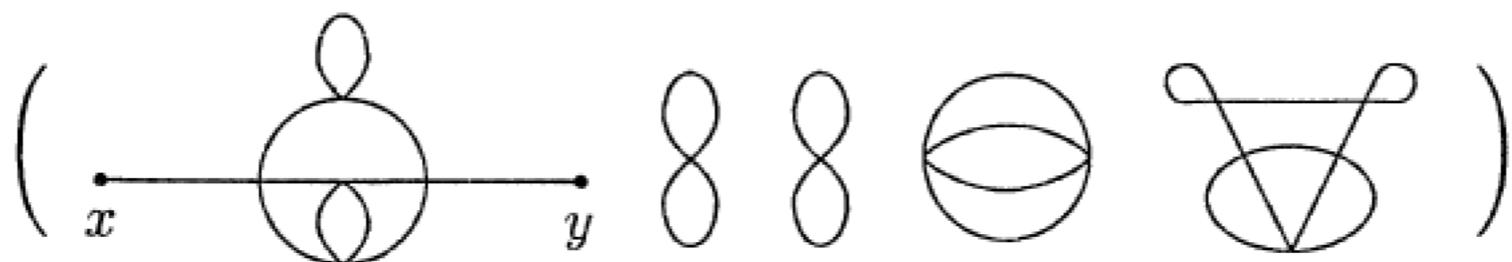

FIG. 2. The measured and theoretical electromagnetic coupling as a function of momentum transfer Q . The solid and dotted lines correspond to positive and negative Q^2 predictions, respectively. As we probe closer to the bare charge, its effective strength increases. $\langle Q_{\gamma_1} Q_{\gamma_2} \rangle^{1/2}$ denotes the square root of the median value for the product of the photon momentum transfers in the antitagged $e^+e^- \rightarrow e^+e^-\mu^+\mu^-$ sample. The hadronic data point has been shifted for display.

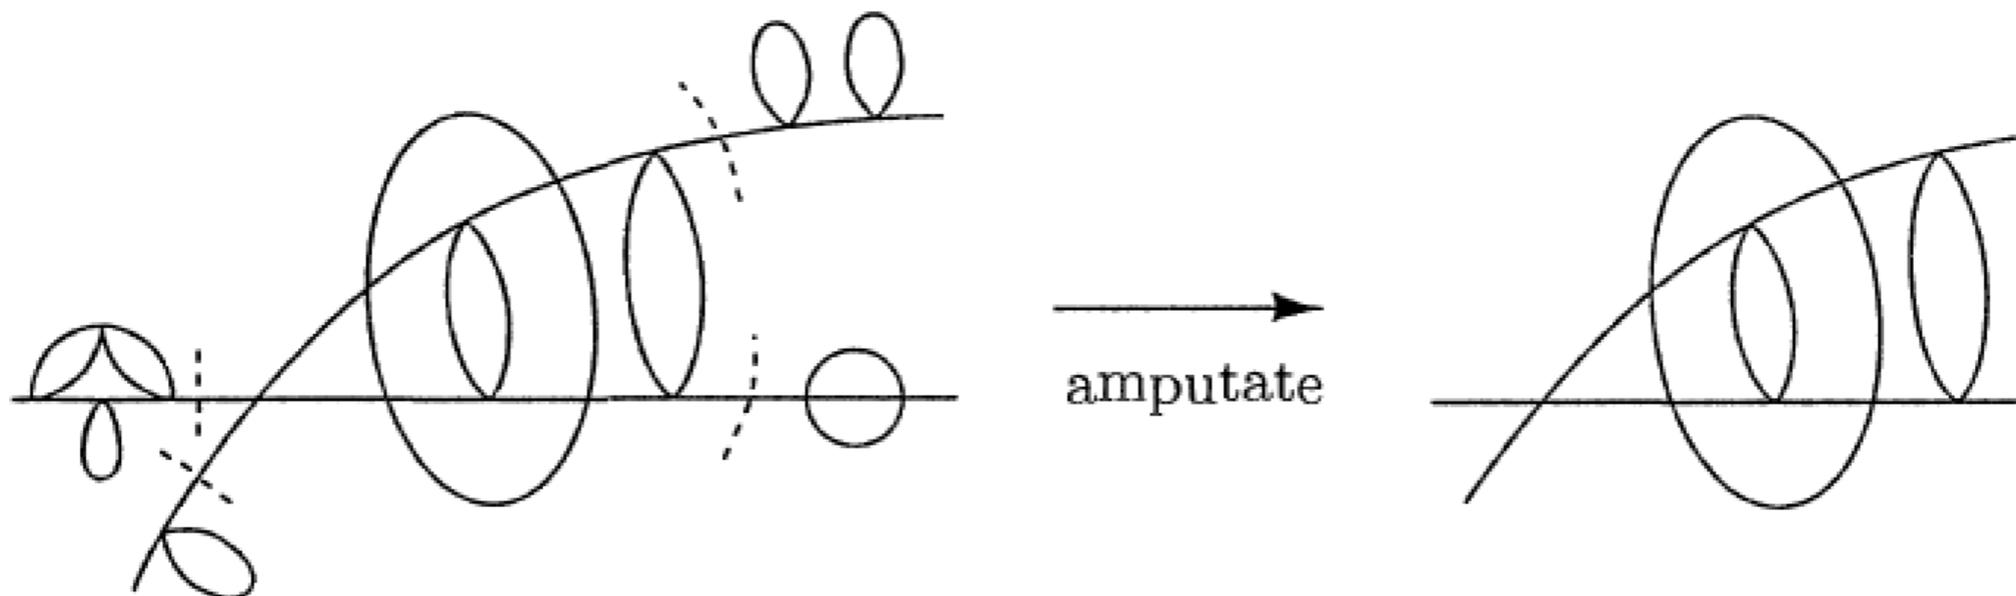

Complements

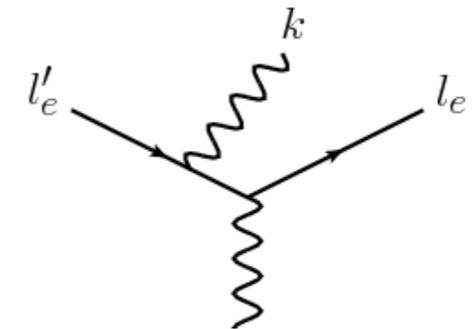

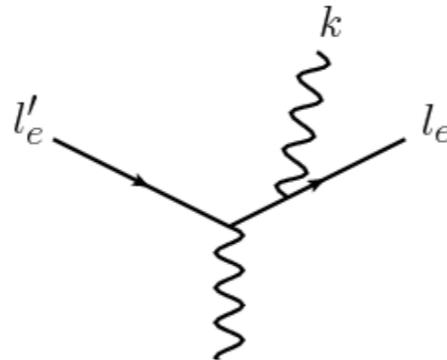

- For a given process the amplitudes of all diagrams with identical input and output particles should be summed
- Not connected diagram should be removed

- Only amputated diagrams (*i.e.* no loops on an external leg)

Elastic scattering of an electron

Well known problem: soft photon emission diverges at low k
Regularise with soft photon mass μ

$$d\sigma(p \rightarrow p' + \gamma) = d\sigma_0(p \rightarrow p') \times \alpha / \pi f_{\text{IR}}(q^2) \log(-q^2 / \mu^2)$$

NB: $f_{\text{IR}}(q^2 \rightarrow -\infty) = \log(-q^2 / m_e^2)$
double logarithm!

Compensates precisely the IR divergence from the vertex!

$$\delta F_1^{\text{IR}}(q^2) = -\alpha / (2\pi) f_{\text{IR}}(q^2) \log(-q^2 / \mu^2)$$

Can not measure elastic scattering independently from soft bremsstrahlung emission

$$d\sigma_{\text{meas}}(p \rightarrow p') \equiv d\sigma(p \rightarrow p') + d\sigma(p \rightarrow p' + \gamma(k < E_{\text{min}}))$$

$$d\sigma_{\text{meas}}(p \rightarrow p') \equiv d\sigma_0(p \rightarrow p') [1 - \alpha / \pi f_{\text{IR}}(q^2) \log(-q^2 / E_{\text{min}}^2)]$$

where E_{min} is the minimal energy one can measure for a photon
 μ dependence has disappeared...

Emission of n soft photons adds terms $[\alpha / \pi (-q^2 / m_e^2) \log(-q^2 / \mu^2)]^n$
 Summing the logarithm to get to the Sudakov form factor

$$d\sigma_{\text{meas}}(p \rightarrow p') \equiv d\sigma_0(p \rightarrow p') \times$$

$$| \exp[-\alpha / \pi f_{\text{IR}}(q^2) \log(-q^2 / E_{\text{min}}^2)] |^2$$
